

Photo-z comparison

# Aperture Flux

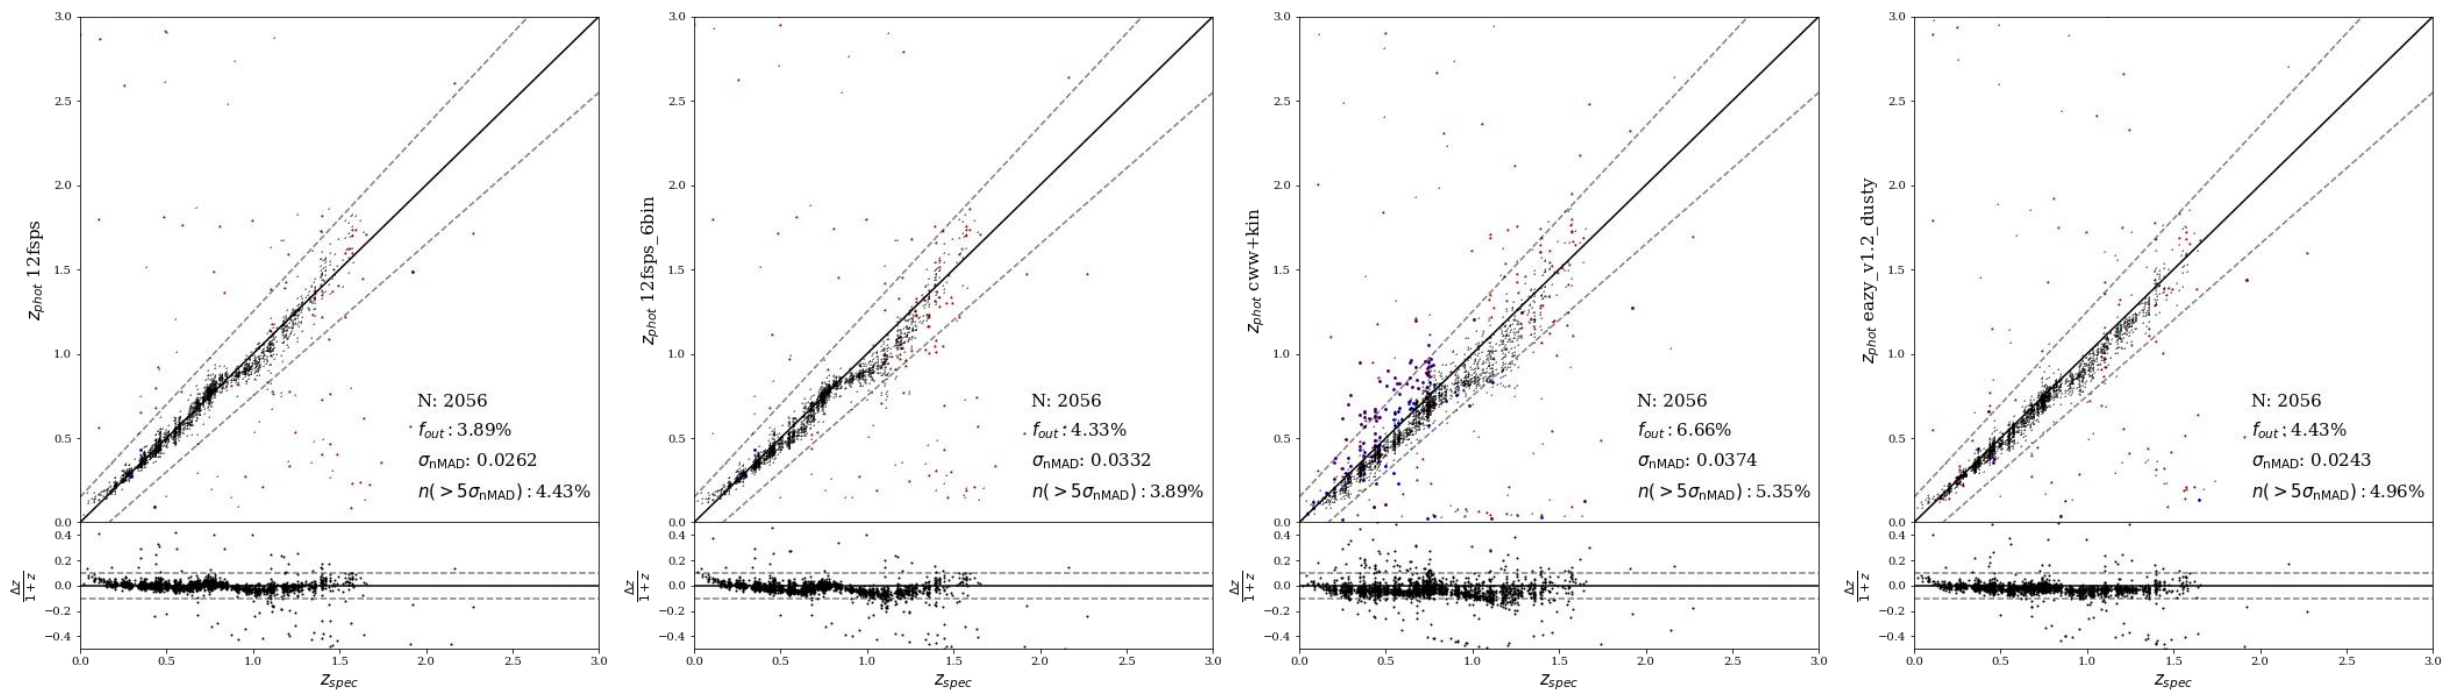

- PSF: constructed by the median value of scores of point sources
- aperture flux: flux in adaptive aperture
  - min\_aper: determined by FWHM of PSF
- total flux: aperture flux corrected by PSF
- Flux error:  $\sigma = \sqrt{\sigma_{bkg}^2 + \frac{f_{aper}}{gain}}$
- Total flux error: same correction as total

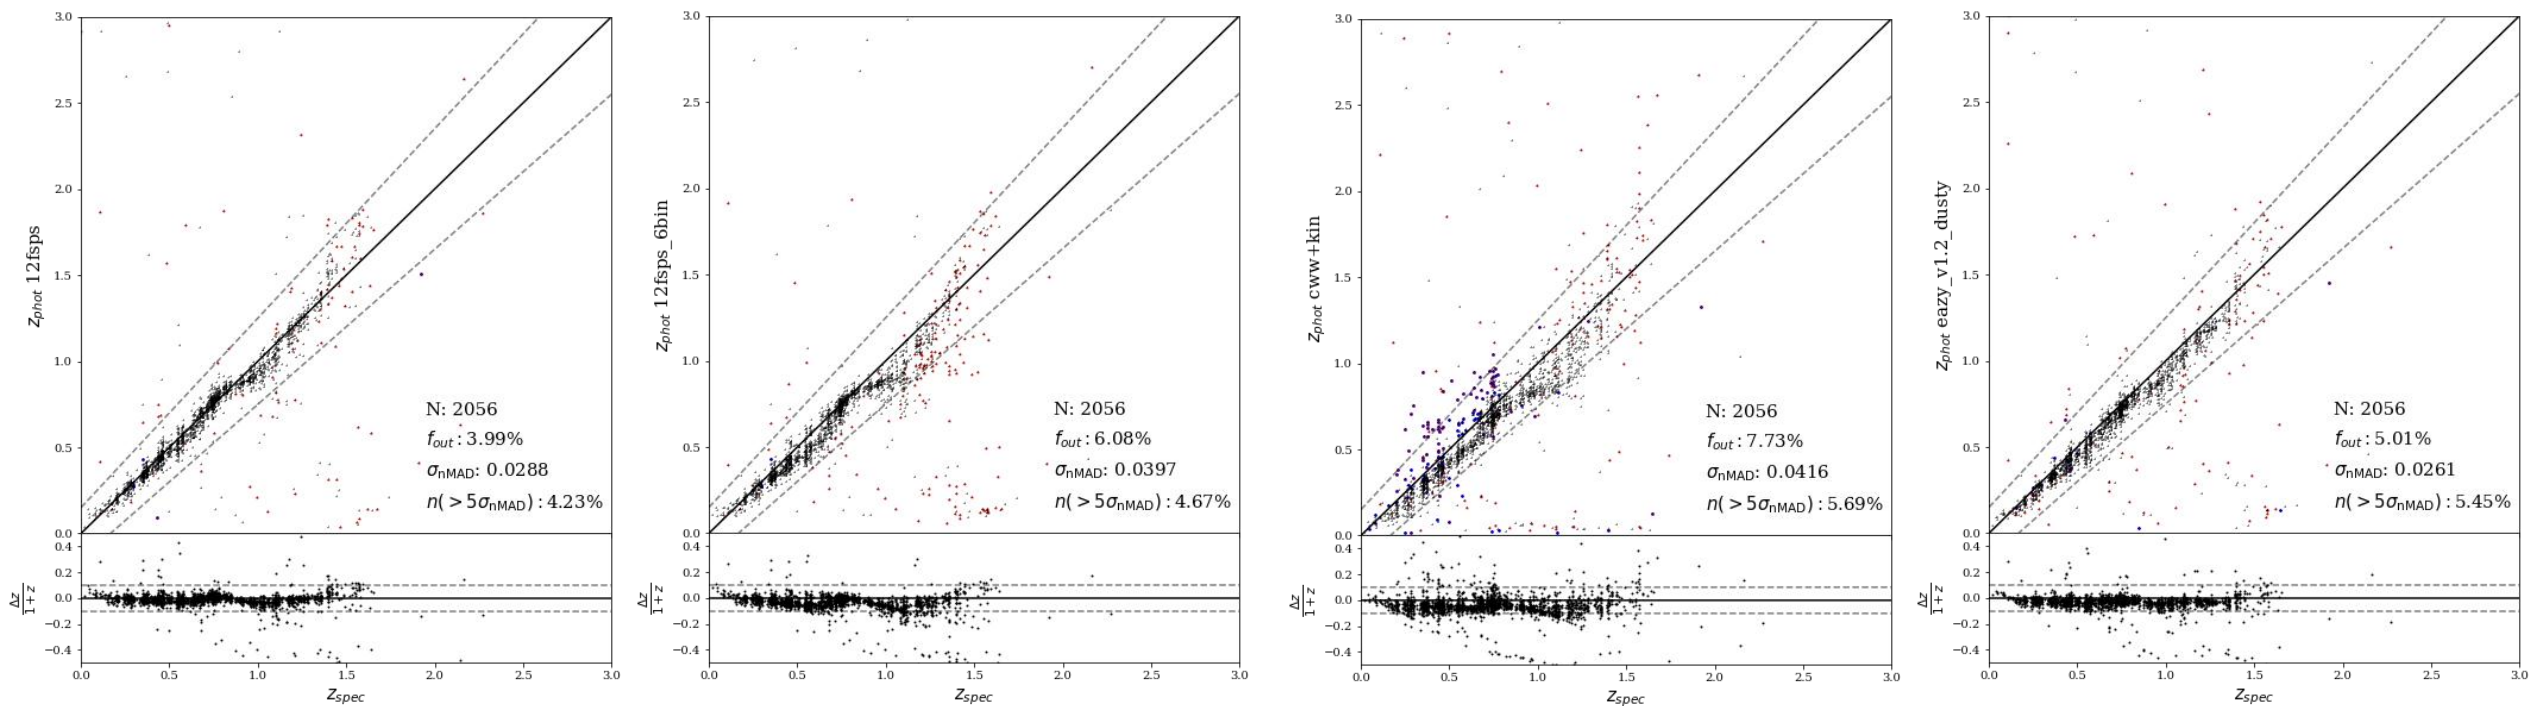

- Outlier fraction:  $\left| \frac{z_{\text{phot}} - z_{\text{spec}}}{1 + z_{\text{spec}}} \right| > 15\%$
- $\sigma_{nMAD} = \textit{median} \left( \left| \frac{z_{\text{phot}} - z_{\text{spec}}}{1 + z_{\text{spec}}} \right| \right)$

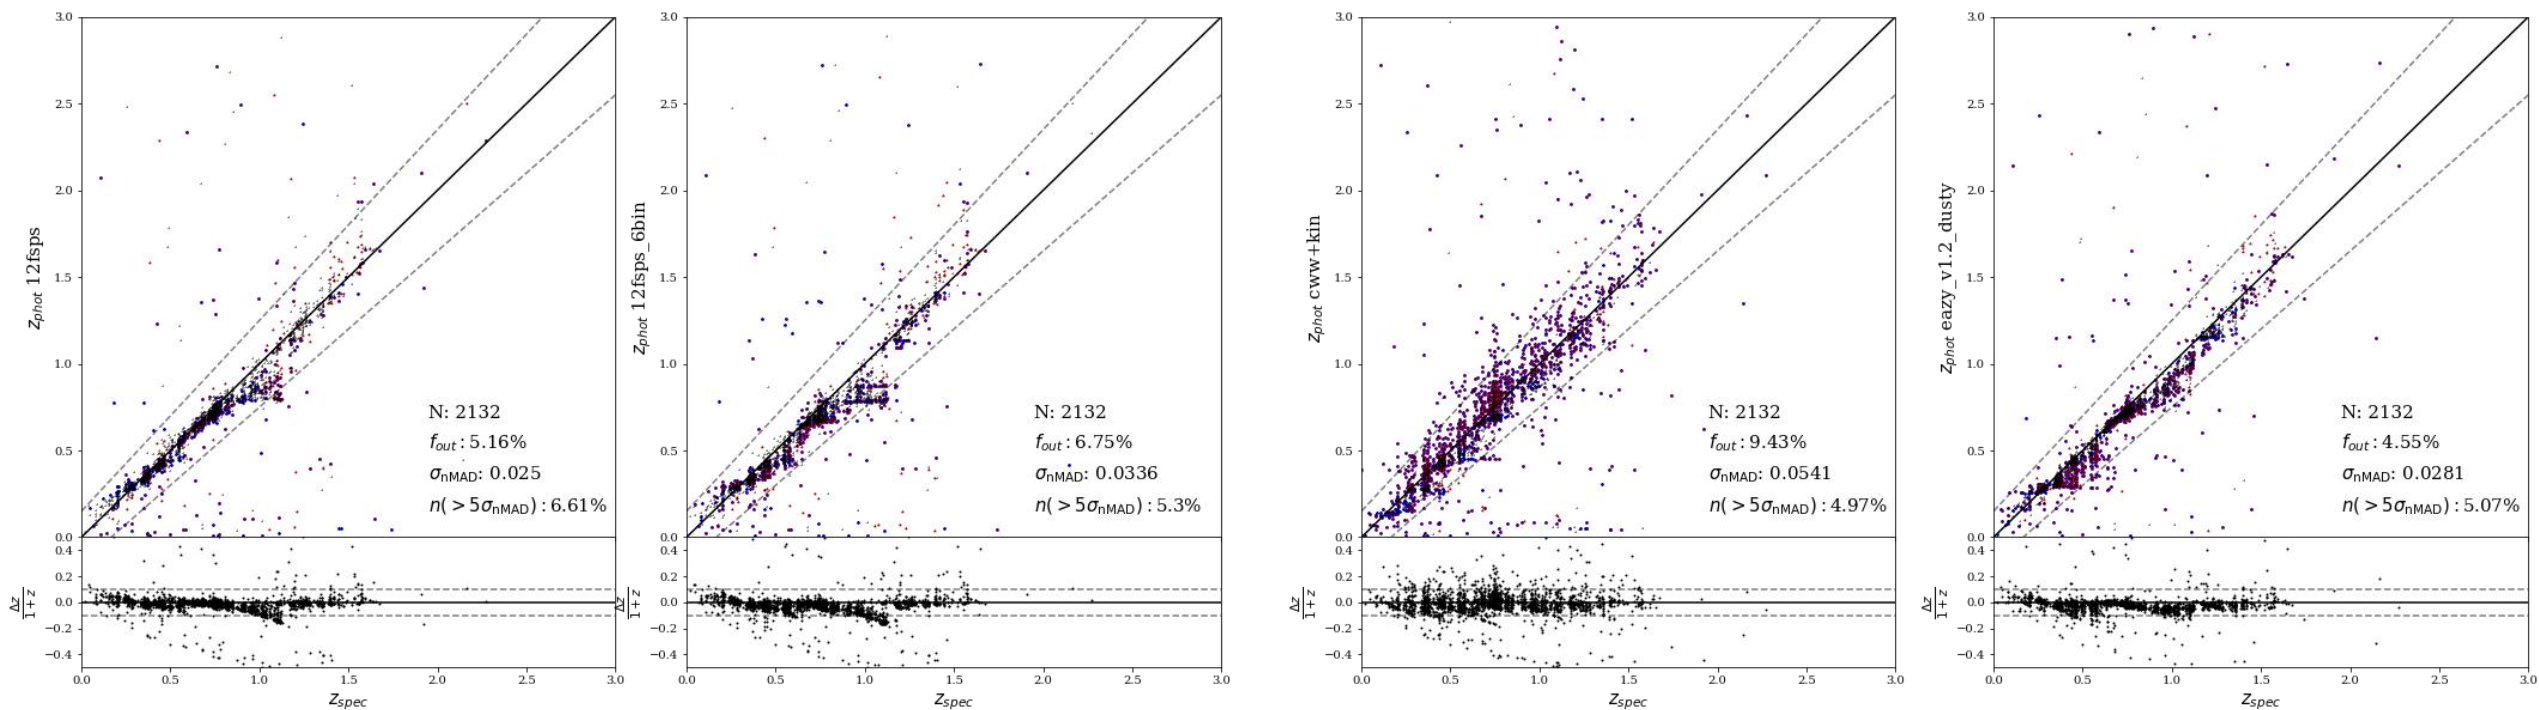

# Photo-z with aperture flux

# Photo-z with aperture flux no prior

# Photo-z with Stefanon+2017 flux catalog

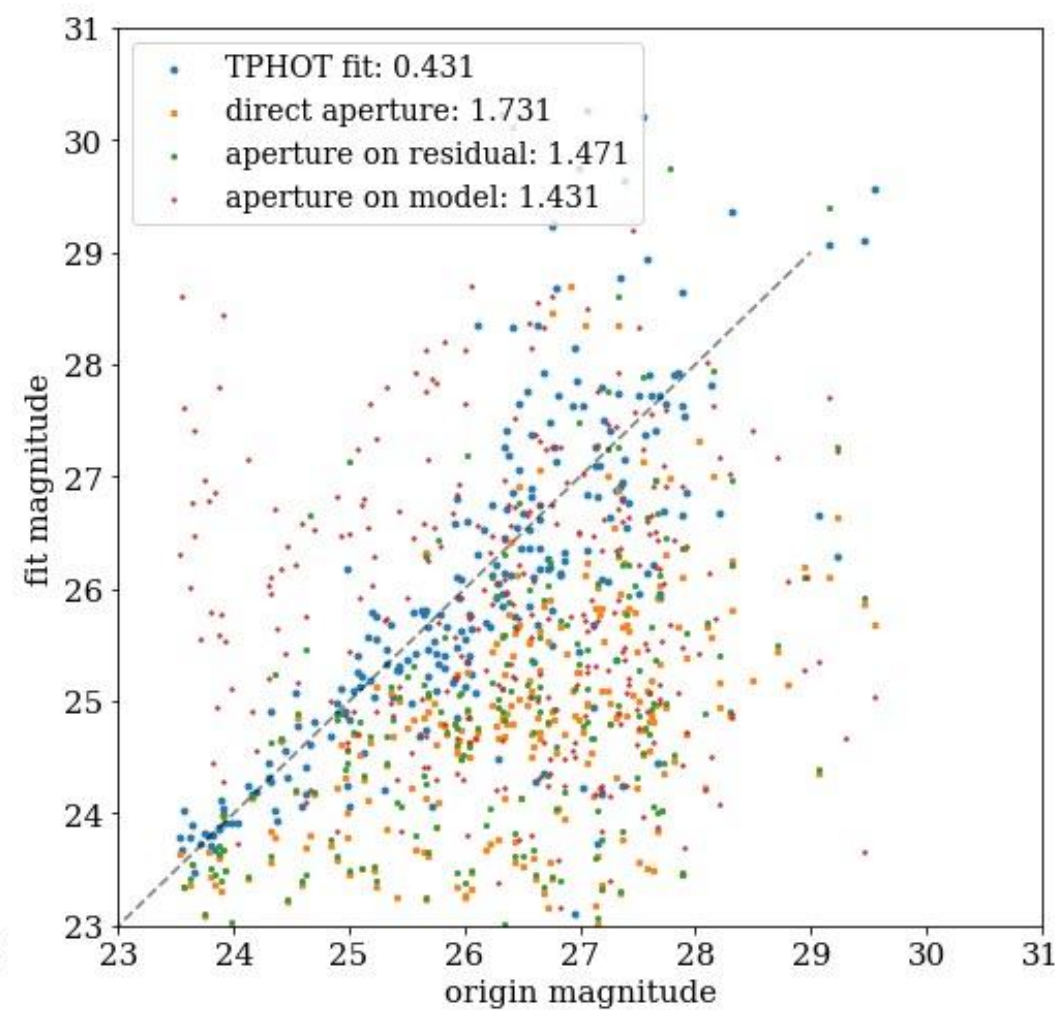

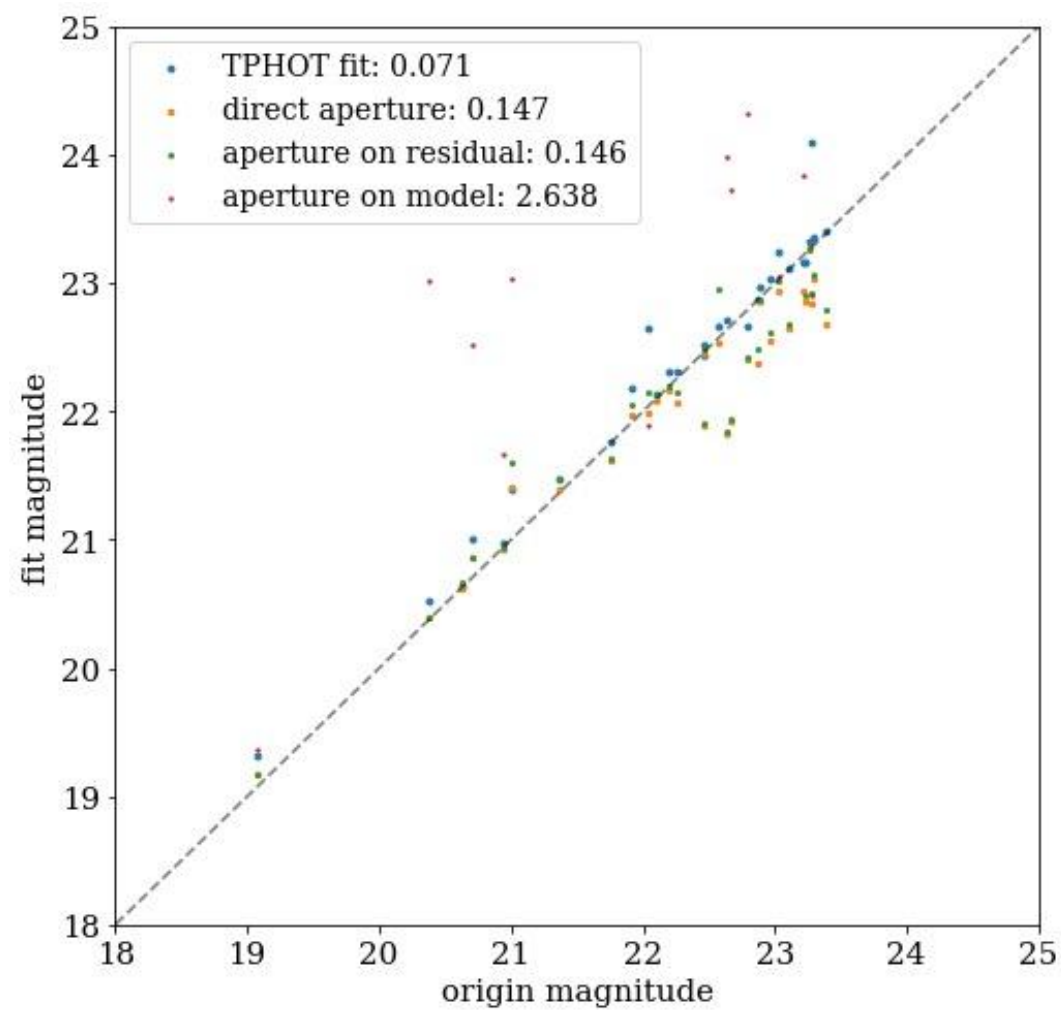

# Photo-z with Stefanon+2017 flux catalog no prior

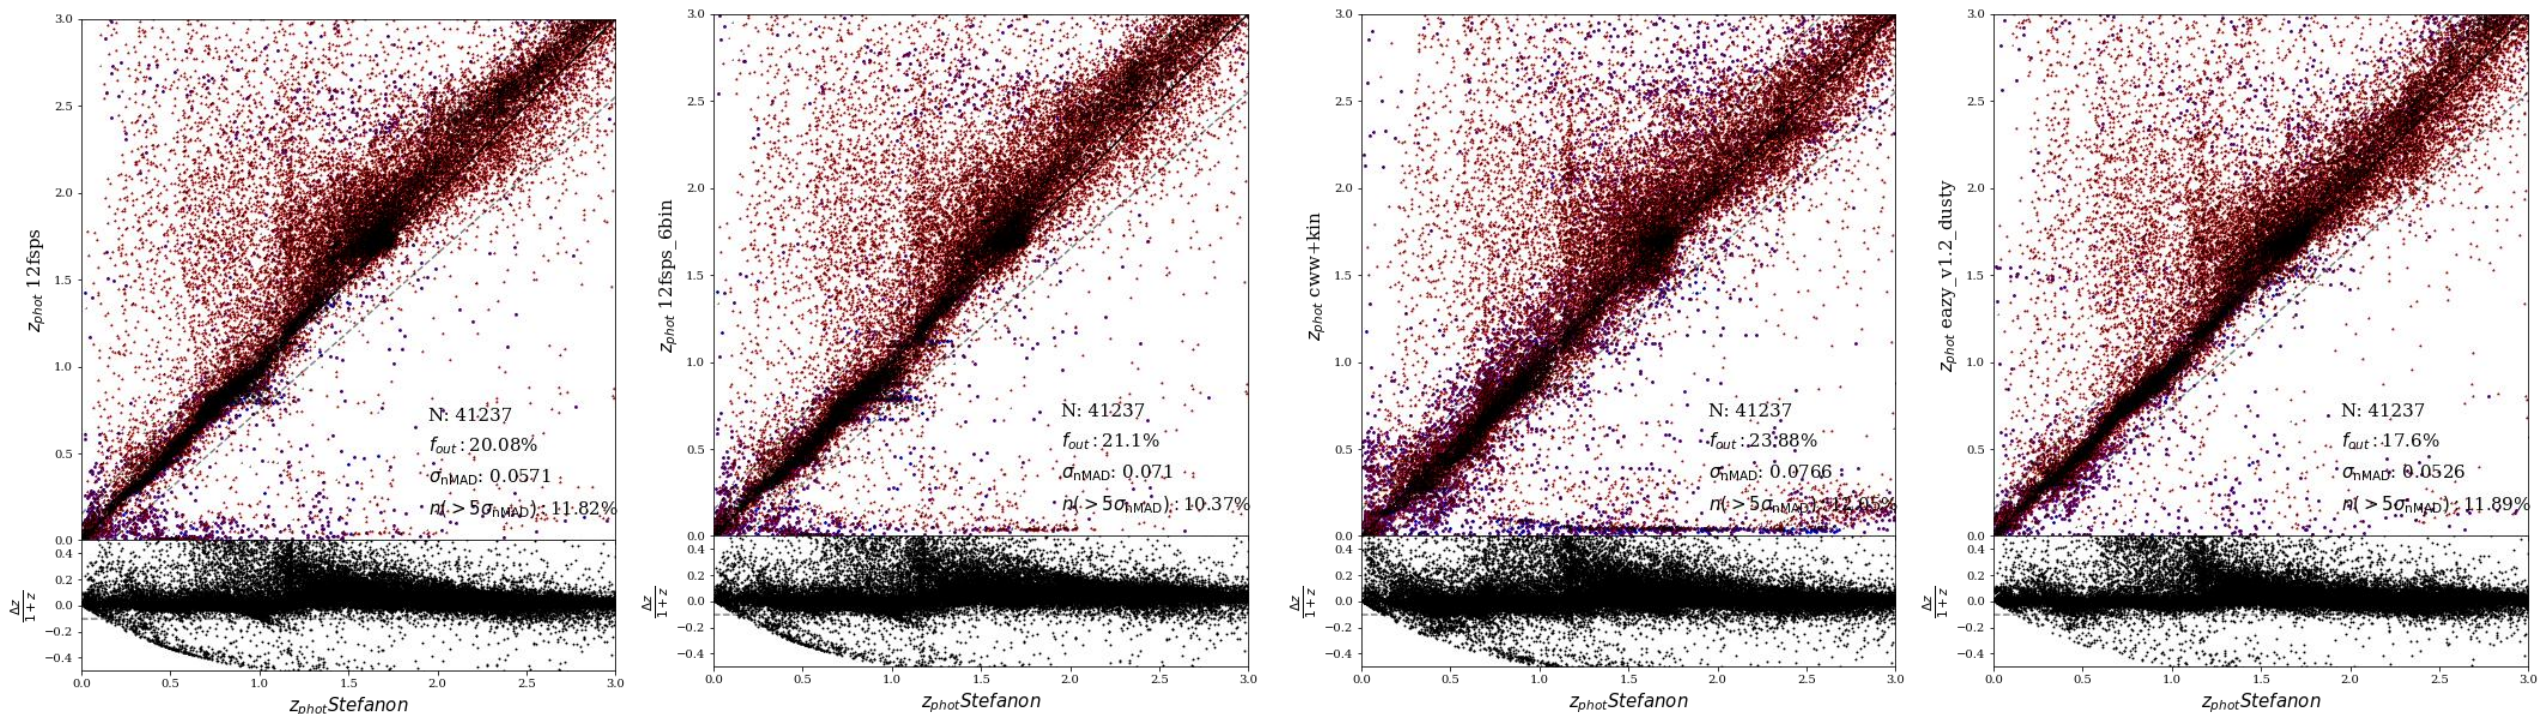

Outlier fraction $\sigma_{nMAD}$	With f160w prior		Without f160w prior	
	Stefanon+17	Aperture flux	Stefanon+17	Aperture flux
12FSPS	5.16% 0.0250	3.89% 0.0262	5.35% 0.0303	3.99% 0.0288
12FSPS+6bin	6.75% 0.0336	4.33% 0.0332	7.32% 0.0343	6.08% 0.0397
CWW+KIN	9.43% 0.0541	6.66% 0.0374	9.85% 0.0549	7.73% 0.0416
Eazy_v1.2_dusty (default)	4.55% 0.0281	4.43% 0.0243	4.64% 0.0280	5.01% 0.0261

# Eazy photo-z from Stefanon flux catalog v.s. Stefanon photo-z catalog

Blue point means high chi-square;  
Red point means high  $q_z$ .

High specz objects

# Photo-z with aperture flux

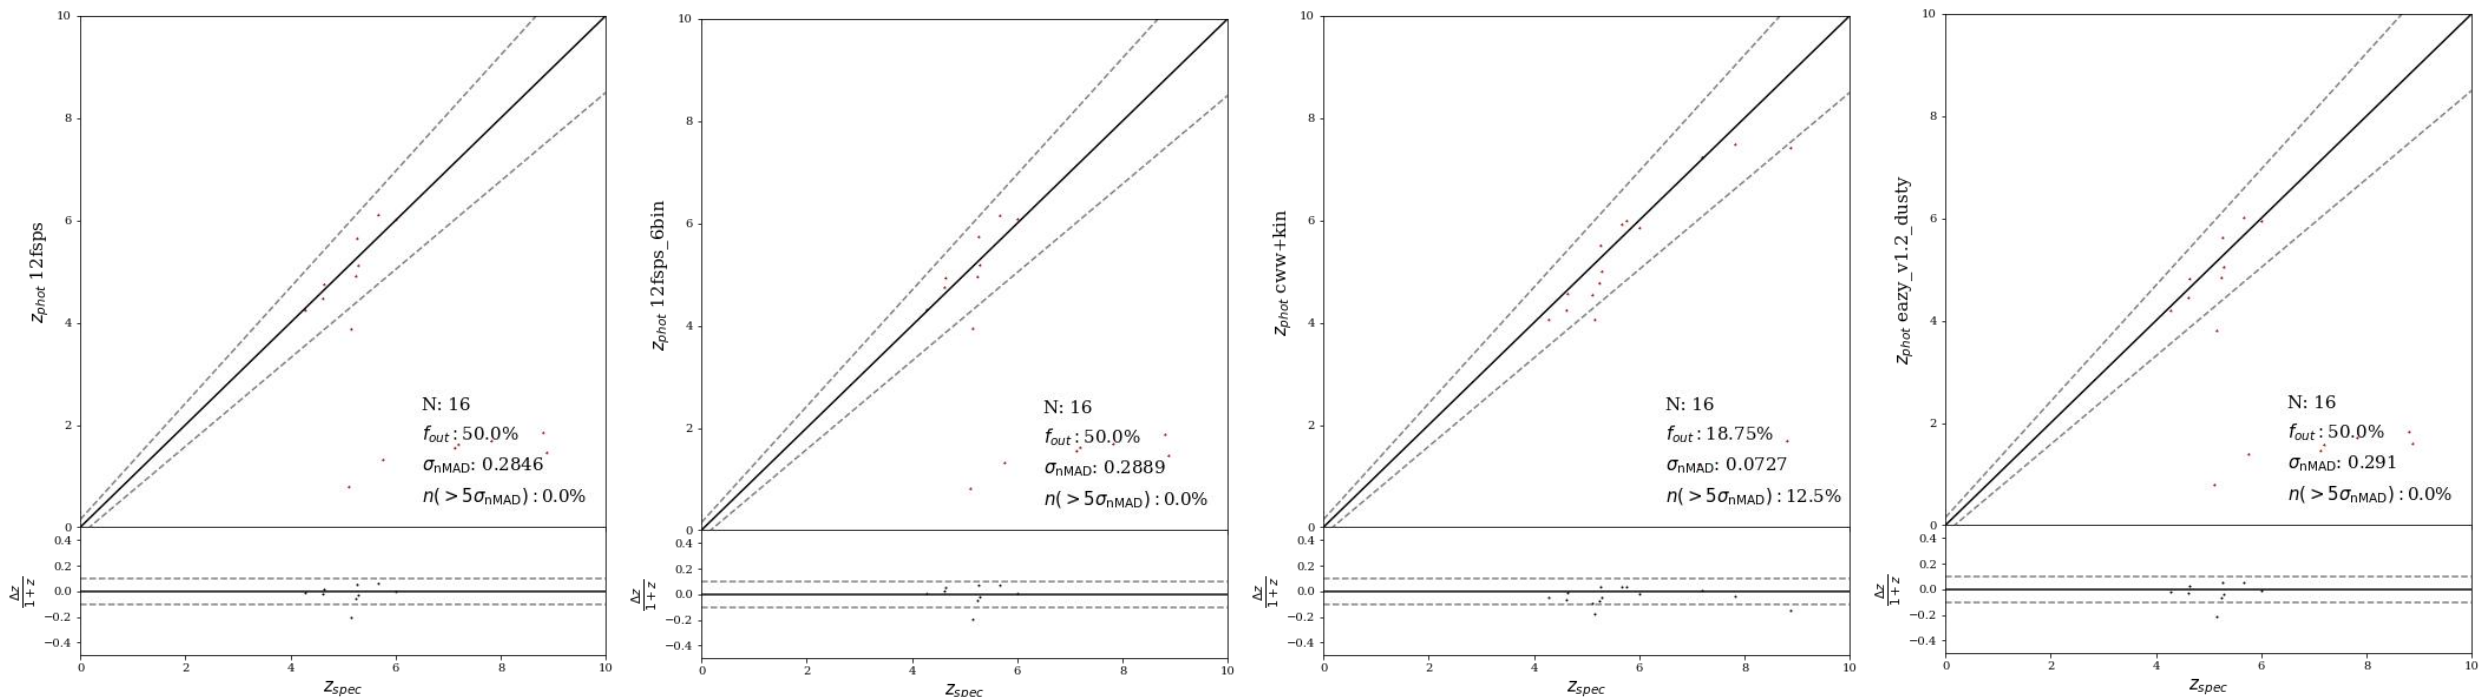

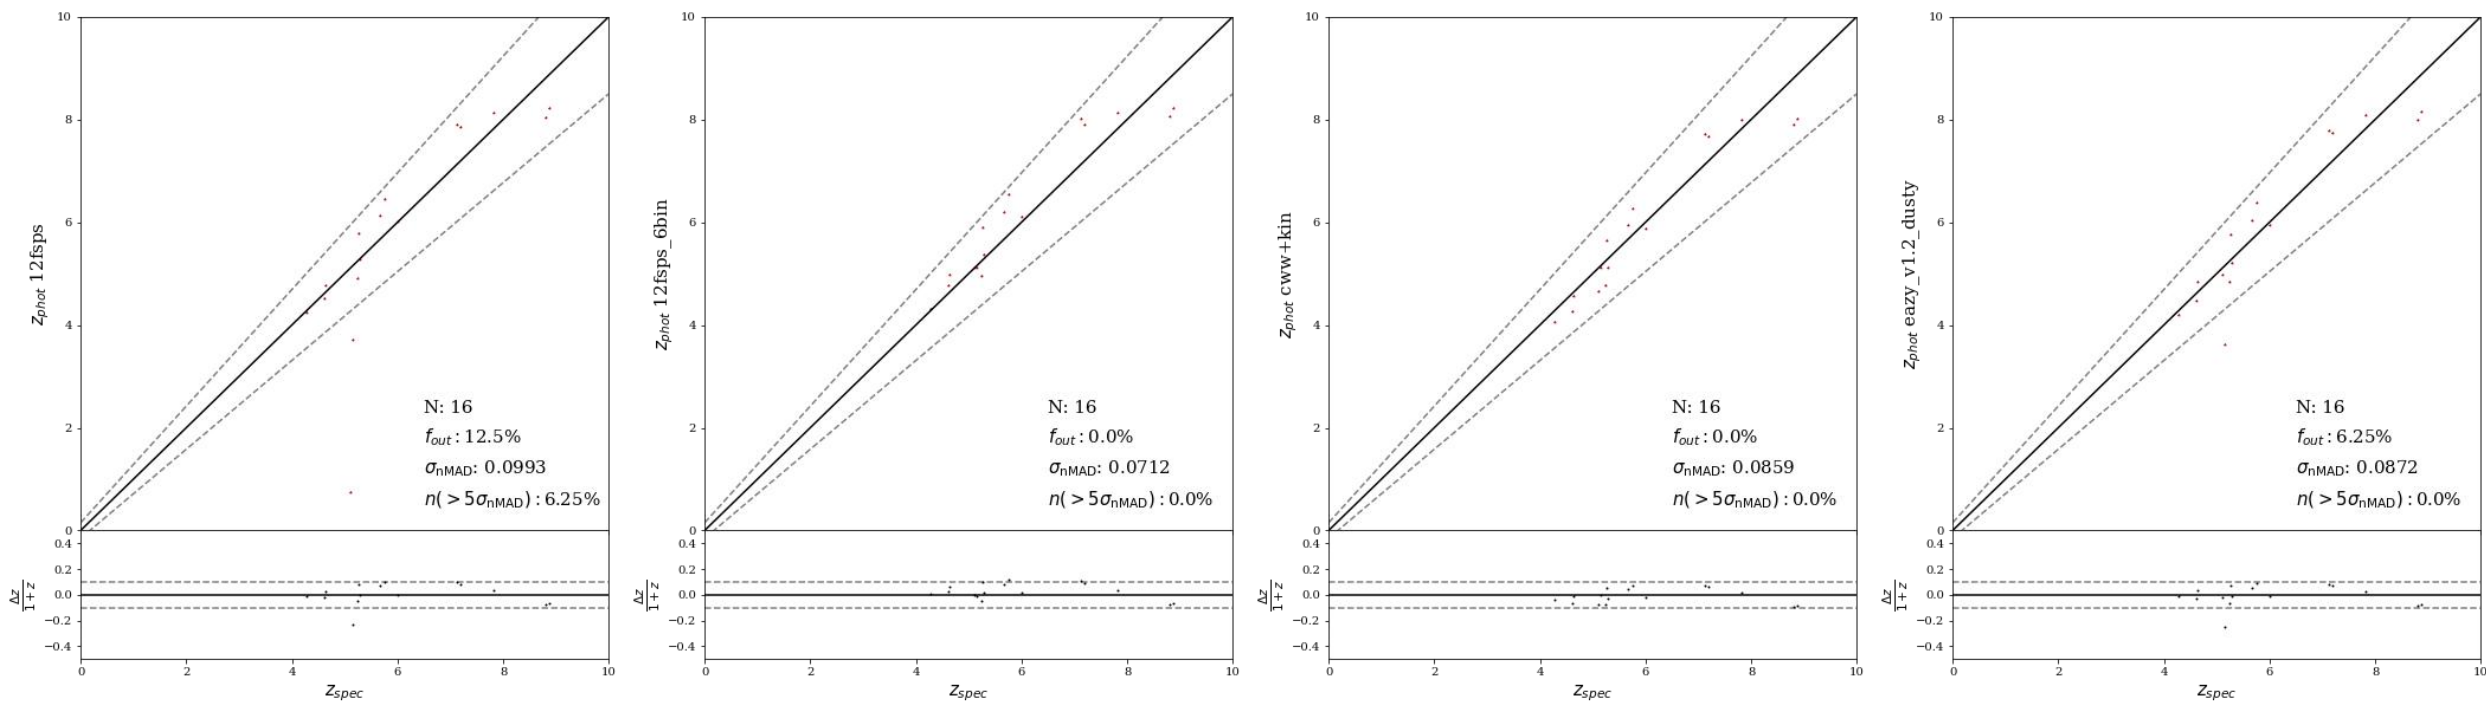

# Photo-z with aperture flux no prior

# Photo-z with Stefanon+2017 flux catalog

# Photo-z with Stefanon+2017 flux catalog no prior

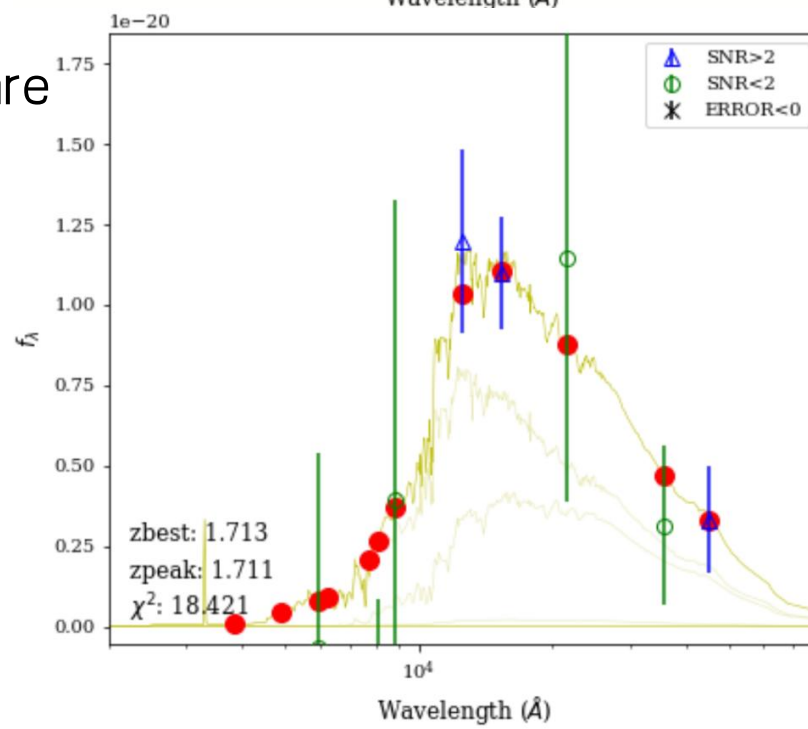

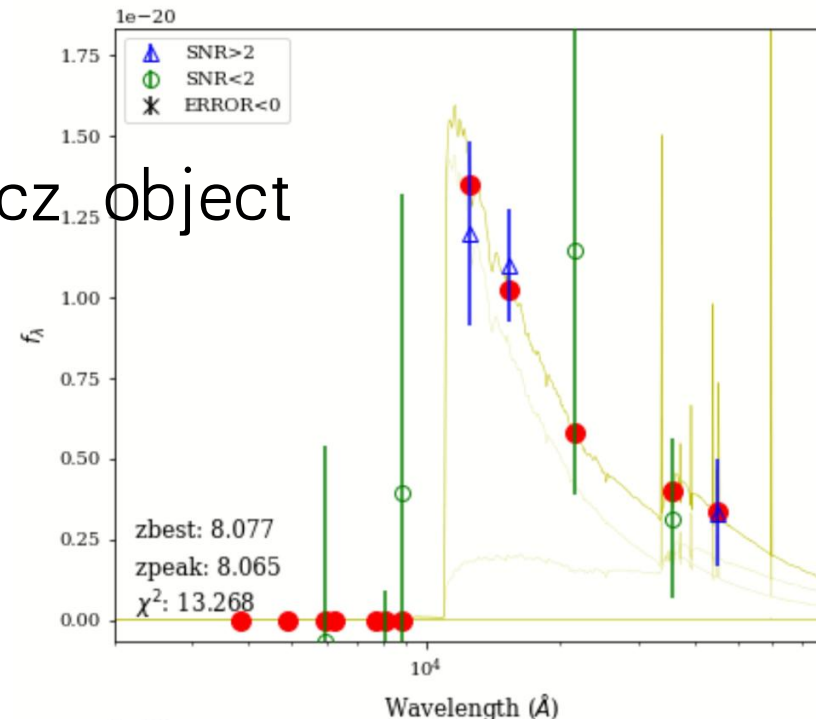

# A example of high-specz object

Upper panel: without prior  
Lower panel: with prior

Maybe we can use chi-square  
to choose better photo-z.

- For faint source in HST image, we need use TPHOT or other software to fit the flux;
- For bright source, aperture flux and fitting flux have no significant difference.
- For faint sources we need calculate photo-z with/without prior at the same time, to determine which one is better.
